SnapText Rx

Read handwritten prescriptions faster — and check every line

User Guide · Safety · Tips

Transcription aid — not a clinical decision tool. Every medicine must be checked against the original prescription by a qualified person before use.

Version 1.0 · Alkhair Soft · Created by Kamran Yousaf Dehlvi, Product Creator & Lead Architect

1. What SnapText Rx does

SnapText Rx reads a photo, scan or screen snip of a prescription — including handwriting — and turns every medicine line into a card for you to check: the medicine, strength, how often, for how long and any instructions such as *after meals*. It suggests medicine names from a list of about 4,800 names, flags names it is unsure about, and only lets you copy or export once **you** have confirmed every line.

> It runs entirely on your computer. Prescriptions and patient details never leave the PC.

What it is not

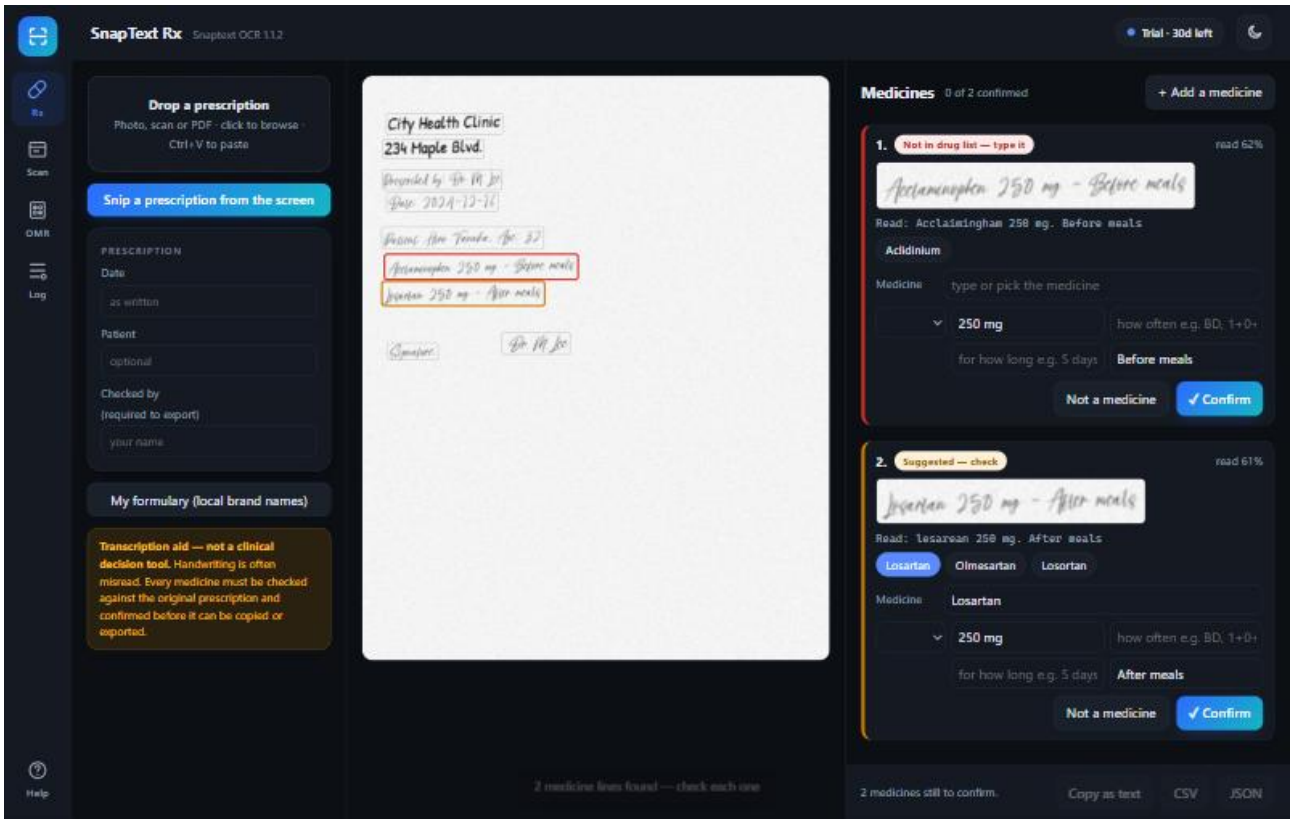

- Not a medical device and not a clinical decision tool.
- It does not check doses, interactions, allergies or whether a prescription is appropriate.
- It does not replace a pharmacist, doctor or any qualified person.

Install

1. Run **SnapText-Rx-Setup.exe**. If Windows shows *Windows protected your PC*, click **More info** → **Run anyway**.
2. Read the **Intended use and safety** page and click **I understand**.
3. Click **Install**, then **Launch SnapText Rx**. The handwriting model is included.

SnapText Rx installs next to Snaptext without affecting it. Each has its own trial and licence.

2. Reading a prescription

1. Drop a photo or scan of the prescription on the left panel — or click it to browse, paste with `Ctrl + V`, or click **Snip a prescription from the screen**.
2. SnapText Rx reads it with two handwriting readers (about two seconds per handwritten line). The prescription appears in the middle with each medicine line outlined.
3. On the right, each medicine has a card with the **crop of the handwriting** and what was read. Check it against the crop: pick or type the medicine, correct the strength, frequency, duration and instructions.
4. Click **✓ Confirm** on each card. Lines that are not medicines: **Not a medicine**. Missed a line? **+ Add a medicine**.
5. Enter your name under **Checked by**. Now **Copy as text**, **CSV** and **JSON** unlock.

3. Reading the status of each line

Status	What it means	What you do
In drug list	The word read is exactly a known medicine name.	Still compare with the handwriting, then confirm.
Suggested — check	The word read was close to one known name, which is filled in for you. The word as read is shown above it.	Check it carefully; change it if wrong.
Look-alike — choose	Two or more medicine names are about equally close (e.g. Hydroxyzine / Hydralazine). Nothing is filled in.	Pick the one on the prescription.
Unsure — pick or type it	No close enough match to fill in. Possible names are shown as buttons only.	Type the medicine (the box suggests names as you type).

Changing anything on a confirmed card un-confirms it, so nothing is exported that you haven't checked after your last change.

Two readers

Each medicine line is read twice: by a general handwriting reader and by one trained on real prescriptions. A medicine is only filled in for you when both agree; when they disagree the card shows **Second reading** and offers both readings' names. In tests on real doctors' handwriting this kept wrong-but-filled-in rows to about 1 in 100 while finding the right medicine first about 6 times in 10.

What gets exported

Every export includes the checker's name, the date and time, the prescription date and patient (if you entered them), each medicine as you confirmed it, and each line *as read* — so a second person can audit the transcription.

4. My formulary — your local brands

The built-in list has about 4,800 names: US FDA ingredient and brand names, international names (Paracetamol, Salbutamol…) and a starter list of brands common in Pakistan. Your pharmacy stocks many more.

1. Click **My formulary** on the left.
2. Add your brand names, one per line — e.g. `Panadol Extra`, `Risek`, `Augmentin DS`.
3. Click **Save**. They are used from the next prescription onwards.

> The more of your stock is in the formulary, the more lines come back as **In drug list**.

5. Tips for good results

- Photograph the prescription flat, in good light, filling the frame.
- One prescription per image; for a PDF, only page 1 is read.
- English and Latin-script medicine names are read; Urdu text is not.
- Real doctors' handwriting is hard: expect more *type it* and *look-alike* rows than on neat writing. That is SnapText Rx being careful, not failing.

6. Trial and licence

SnapText Rx is free to try for 30 days, then 3 prescriptions a day until licensed. Click the licence chip at the top right, copy your **Machine ID** and send it to Alkhair Soft to receive a SnapText Rx licence. A Snaptext licence does not unlock SnapText Rx.
